Why Most People Miss 80% of Claude Code

Most developers use Claude Code the same way they use a chat interface. They type a prompt, read the response, type another prompt. That works. But it leaves most of the tool untouched.

Claude Code ships with a full command system via slash commands. Each one is a shortcut to a specific workflow: running your app, reviewing your code, scheduling agents, looping on a task. The commands are not cosmetic. They change what Claude can do and how it operates.

The difference between a casual user and a power user is not how they prompt. It is which commands they reach for first and which ones they have never opened.

There are roughly 15 slash commands worth knowing. Most people use two or three. This guide ranks all of them, explains what each one actually does, and shows you which ones to build your workflow around.

A quick note on how to read the tiers:

- S Game changers**
High-leverage commands that save real time. Should be in every workflow.
- A Daily drivers**
High value, use them regularly. Most developers underuse these.
- B Situational**
Solid when you need them. Not every session, but worth knowing.
- C Occasional**
Good to know they exist. You will use them once and forget until you need them again.
- D Rarely touched**
Set and forget, or just never.

02

The Full Tier List: S to D

S TIER

Game Changers

These save hours. Should be in every workflow, every session.

- `/code-review ultra`: multi-agent cloud review of your entire PR
- `/init`: Claude reads your codebase and writes its own context file
- `/run`: opens your app and tests it like a human would

A TIER

Daily Drivers

High value. Most developers underuse every command on this list.

- `/verify`: confirms your fix works end to end before you push
- `/security-review`: scans your diff for vulnerabilities
- `/loop`: sets Claude on a recurring task autonomously
- `/simplify`: removes complexity you added but did not need

B TIER

Situational

Solid utility. Not every session, but worth knowing cold.

- `/schedule`: cloud agents on a cron job
- `/compact`: summarizes bloated context without losing the thread
- `/review`: standard PR review (non-ultra)
- `/code-review`: lower effort levels for quick scans

C AND D TIER

The Rest

C: good to know they exist. D: set it once or never.

- `/memory`: saves facts across sessions (you will forget to use it)
- `/config`: settings, touched once
- `/cost`: token usage tracker
- `/help`: you are past this if you are reading this guide
- `/vim`: nobody asked

The tier is determined by one question: how much leverage does this command give you per minute spent? S tier commands change the output quality of your whole session. D tier commands change a setting.

03 + 04

S and A Tier Deep Dive + Daily Workflow

S TIER

The Three You Should Always Use

- **/init** first, every new project. Claude writes CLAUDE.md so every future session starts with full context.
- **/run** after any UI or feature change. It opens the app and tests it. Not just compile. Does it work.
- **/code-review ultra** before any PR merge. Multi-agent. It finds things you missed.

[START HERE](#)

A TIER

The Four That Are Underrated

- **/verify** after a bug fix. Confirms the fix works end to end, not just in isolation.
- **/security-review** before shipping. Scans your diff for OWASP issues automatically.
- **/loop** for any repeating task. Set it, come back when done. Async by default.
- **/simplify** after any refactor. Removes the complexity you added without realising.

[ADD NEXT](#)

The Recommended Daily Stack

Start session

- **/init** on any new project to write the context file

Build

- prompt normally, then **/run** to verify the change works in the real app

Fix

- **/verify** after any bug fix, **/simplify** after any refactor

Ship

- **/security-review** on the diff, **/code-review ultra** before the PR

Automate

- **/loop** or **/schedule** for anything recurring
